#### Autumn Semester, 2024

#### Outline

- Regression as a means of minimising sum of the squared errors
- Regression assumptions what they mean, how they can be used for validation and model building
- Case studies from Advertising and Credit Balance prediction

# Overview — Summary

- 1. Introduction
- 2. Regression1 review
- 3. Case Study 1: Generated
- 4. Case Study 3: Advertising
- 5. Case Study 4: Credit Balances
- 6. Multivariate Analysi
- 7. Review and Summary
- 8. Resource

This week's aim is to continue the introduction to linear regression, focusing more on how to deal with problems with more challenging datasets.

• Examine some extensions to the simplest case of linear regression.

- Examine some extensions to the simplest case of linear regression.
- We introduce two new concepts: dimensionality reduction and regularisation

- Examine some extensions to the simplest case of linear regression.
- We introduce two new concepts: dimensionality reduction and regularisation
- To provide context we will use the following datasets:

- To provide context we will use the following datasets:
  - Generated data (various)
  - Advertising dataset: predicting widgets sold based on spending in different advertising channels
  - Credit dataset: predicting credit balance using income, status, etc.

### Definition 1 (Linear Regression Assumptions)

• The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .

- The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .
- **②** The residual errors  $\epsilon$  are drawn from a (multivariate) Normal distribution  $N(\mu, \sigma^2)$  where  $\mu = \mathbf{0}$ .

- The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .
- **③** The residual errors  $\epsilon$  are drawn from a (multivariate) Normal distribution  $N(\mu, \sigma^2)$  where  $\mu = 0$ .
- **①** The predictors are not pairwise collinear, i.e., each pair of predictors  $\beta_{j_1}$  and  $\beta_{j_2}$  (associated with columns  $X(:,j_1)$  and  $X(:,j_2)$ ) have low correlation (equivalently, the inner product of  $X(:,j_1)$  and  $X(:,j_2)$  is far from zero).

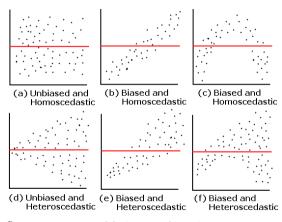

- The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .
- **②** The residual errors  $\epsilon$  are drawn from a (multivariate) Normal distribution  $N(\mu, \sigma^2)$  where  $\mu = 0$ .
- **②** The predictors are not pairwise collinear, i.e., each pair of predictors  $\beta_{j_1}$  and  $\beta_{j_2}$  (associated with columns  $X(:,j_1)$  and  $X(:,j_2)$ ) have low correlation (equivalently, the inner product of  $X(:,j_1)$  and  $X(:,j_2)$  is far from zero).
- There is no auto-correlation in y: each observation is independent of its "neighbours".

- The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .
- **3** The residual errors  $\epsilon$  are drawn from a (multivariate) Normal distribution  $N(\mu, \sigma^2)$  where  $\mu = 0$ .
- **1** The predictors are not pairwise collinear, i.e., each pair of predictors  $\beta_{j_1}$  and  $\beta_{j_2}$  (associated with columns  $X(:,j_1)$  and  $X(:,j_2)$ ) have low correlation (equivalently, the inner product of  $X(:,j_1)$  and  $X(:,j_2)$  is far from zero).
- There is no auto-correlation in y: each observation is independent of its "neighbours".
- **5** The errors are *homoscedastic* (i.e.,  $Var(\epsilon)$  is constant over the range of x or y).

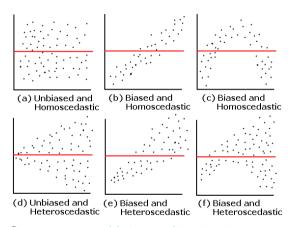

### Definition 1 (Linear Regression Assumptions)

- The underlying relationship between the predictors and the response is linear in the regression parameters  $\beta$ .
- **3** The residual errors  $\epsilon$  are drawn from a (multivariate) Normal distribution  $N(\mu, \sigma^2)$  where  $\mu = 0$ .
- The predictors are not pairwise collinear, i.e., each pair of predictors  $\beta_{j_1}$  and  $\beta_{j_2}$  (associated with columns  $X(:,j_1)$  and  $X(:,j_2)$ ) have low correlation (equivalently, the inner product of  $X(:,j_1)$  and  $X(:,j_2)$  is far from zero).
- There is no auto-correlation in y: each observation is independent of its "neighbours".
- **1** The errors are *homoscedastic* (i.e.,  $Var(\epsilon)$  is constant over the range of x or y).

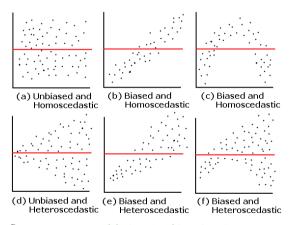

These assumptions can be used constructively, when model building, or as checks, when validating models.

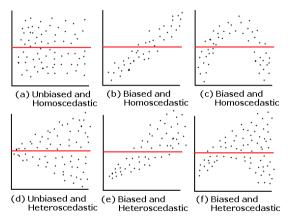

• Bias is caused by underfitting.

  - Using scikit-learn: add the argument sample\_weight = someWeights, e.g., model.fit(Xtrain, yTrain, sample\_weight
  - Using statsmodels: use the weighted version of least squares: WLS not OLS

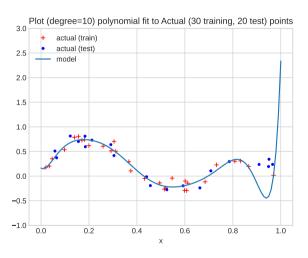

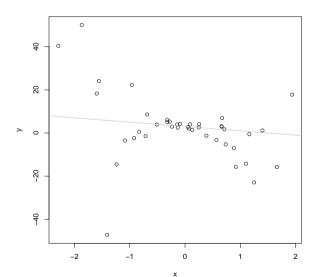

Data is quite noisy

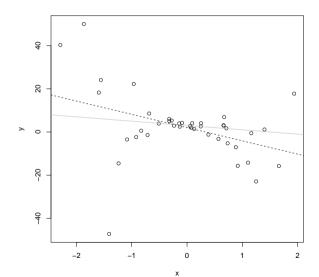

- Data is quite noisy
- Training data has gaps near the edges

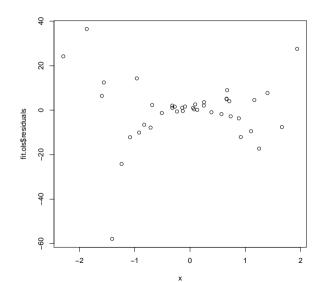

- Data is quite noisy
- Training data has gaps near the edges
- Model may be overfitting

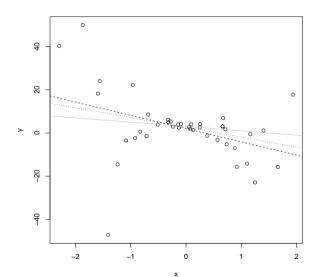

I generated 41 x, y points based on y = 3 - 2x, but with added errors that increase away from x = 0. The plot shows the line with  $\beta = (3, -2)$  in grey.

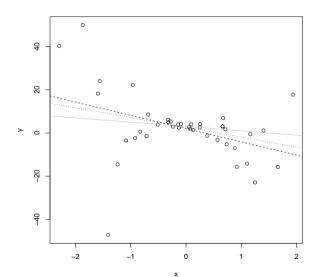

In this plot I added the OLS fit as a dashed line. Note that the parameters of the fit are quite different:  $\beta_{OLS} \approx (2, -6)$ .

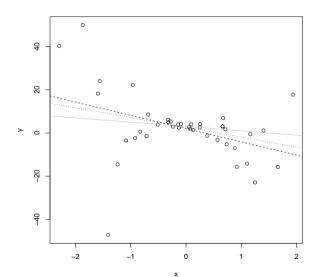

This plot shows how the OLS residuals  $\epsilon_{OLS}$  increase rapidly away from 0, as expected (since this was how the data was generated).

By inspecting the previous residual plot I estimated a weighting function so that the residuals would be "more constant". When this was used to scale the residuals, the resulting Weighted Least Squares estimates were  $\beta \approx (2.6, -4.5)$  (shown as a dotted line) and hence closer to the "true"  $\beta$ .

# Case Study 3: Advertising: Data and Hypotheses

#### TV Radio Newspaper Sales

<b>0</b> 230.1 37.8	69.2	22.1
<b>1</b> 44.5 39.3	45.1	10.4
<b>2</b> 17.2 45.9	69.3	12.0
<b>3</b> 151.5 41.3	58.5	16.5
<u>4</u> 180.8 10.8	58.4	17.9

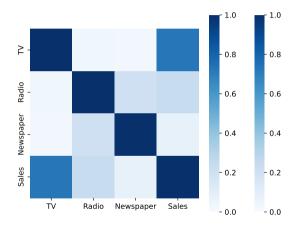

In this data set, the sales figure captures thousands of widgets of a particular type wss sold in a year. Newspaper, Radio and TV represent the annual spend per widget type on the associated advertising channel. The hypothesis is that spend on advertising is a good predictor of sales performance. Since marketing budgets are limited, where should the adverts be placed for maximum sales?

## Case Study 3: Advertising: Looking at the data

Which of the advertising channels appear to have a linear relationship with Sales?

## Case Study 3: Advertising: Collinearity?

Correlation matrix can indicate which attributes should participate in the model as predictors.

A good predictor should have a high correlation with the dependent variable (Sales in this case) and should have low correlation with other candidate predictors.

What are expected to be good predictors for this data?

### The statsmodels way

• The dataframe contains the observed variables

### The sklearn way

• The dataframe contains the (computed) features

### The statsmodels way

- The dataframe contains the observed variables
- The model is specified separately

### The sklearn way

- The dataframe contains the (computed) features
- The model is defined implicitly

### The statsmodels way

- The dataframe contains the observed variables
- The model is specified separately
- Easier to change the model when experimenting

### The sklearn way

- The dataframe contains the (computed) features
- The model is defined implicitly
- Standard interface across all sklearn

#### The statsmodels way

- The dataframe contains the observed variables
- The model is specified separately
- Easier to change the model when experimenting

#### The sklearn way

- The dataframe contains the (computed) features
- The model is defined implicitly
- Standard interface across all sklearn

statsmodels models look like "Sales  $\sim$  TV \* Radio + poly(Newspaper,2)"; notation came from applied statistics community.

#### The statsmodels way

- Start from a "full model" and prune, versus from an "empty model" and add
- We choose the latter, as it is often easier to avoid overfitting

### Example 2 (Forward Selection for Advertising Data)

Define: model score: mean-square-error on the test set for a given model.

● Fit "Sales ~ Newspaper", "Sales ~ Radio", "Sales ~ TV" and calculate their loss values.

- Start from a "full model" and prune, versus from an "empty model" and add
- We choose the latter, as it is often easier to avoid overfitting

### Example 2 (Forward Selection for Advertising Data)

Define: model score: mean-square-error on the test set for a given model.

- lacktriangle Fit "Sales  $\sim$  Newspaper", "Sales  $\sim$  Radio", "Sales  $\sim$  TV" and calculate their loss values.
- ② Choose the best (lowest loss) single-term model ("Sales  $\sim$  TV" in this case), with loss MSE(TV).

- Start from a "full model" and prune, versus from an "empty model" and add
- We choose the latter, as it is often easier to avoid overfitting

### Example 2 (Forward Selection for Advertising Data)

Define: model score: mean-square-error on the test set for a given model.

- lacktriangle Fit "Sales  $\sim$  Newspaper", "Sales  $\sim$  Radio", "Sales  $\sim$  TV" and calculate their loss values.
- $\bullet$  Choose the best (lowest loss) single-term model ("Sales  $\sim$  TV" in this case), with loss MSE(TV).
- $\bullet$  Fit "Sales  $\sim$  TV + Newspaper" and "Sales  $\sim$  TV + Radio" and choose the lowest loss score, which is "Sales  $\sim$  TV + Radio" with loss being MSE(TV + Radio), which is significantly better.

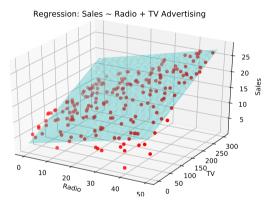

- Start from a "full model" and prune, versus from an "empty model" and add
- We choose the latter, as it is often easier to avoid overfitting

#### Example 2 (Forward Selection for Advertising Data)

Define: model score: mean-square-error on the test set for a given model.

- lacktriangle Fit "Sales  $\sim$  Newspaper", "Sales  $\sim$  Radio", "Sales  $\sim$  TV" and calculate their loss values.
- $\bullet$  Choose the best (lowest loss) single-term model ("Sales  $\sim$  TV" in this case), with loss MSE(TV).
- § Fit "Sales  $\sim$  TV + Newspaper" and "Sales  $\sim$  TV + Radio" and choose the lowest loss score, which is "Sales  $\sim$  TV + Radio" with loss being MSE(TV + Radio), which is significantly better.
- Fit "Sales  $\sim$  TV + Radio + Newspaper". Its loss is the same (MSE(TV + Radio)  $\approx$  MSE(TV + Radio + Newspaper)), so we favour the existing simpler two-term model (Occam's Razor: other things being equal, choose the simplest model.).

# Case Study 3: Advertising: Viewing the Model

Since this two-term model ignores the contribution of the newspaper channel, the Newspaper spend as a contribution to Sales is just another component of the unmodelled (and apparently random) contribution to Sales.

However, the result is a model where the model "explains" 90% of the variance of the data, which is high for an observational study. Why? Can we do better?

• Trying powers of the Radio and TV greater than 1 did not offer much more.

- Trying powers of the Radio and TV greater than 1 did not offer much more.
- However, by adding the TV,Radio interaction so that the model became "Sales ~ TV + Radio +
  TV:Radio" or equivalently "Sales ~ TV \* Radio", the loss decreased significantly, indicating the
  interaction term is valuable.

- Trying powers of the Radio and TV greater than 1 did not offer much more.
- However, by adding the TV,Radio interaction so that the model became "Sales ~ TV + Radio + TV:Radio" or equivalently "Sales ~ TV \* Radio", the loss decreased significantly, indicating the interaction term is valuable.
- All  $\beta$  terms have t-statistic significance of approximately 0.001 which is extremely significant.

- Trying powers of the Radio and TV greater than 1 did not offer much more.
- However, by adding the TV,Radio interaction so that the model became "Sales ~ TV + Radio + TV:Radio" or equivalently "Sales ~ TV \* Radio", the loss decreased significantly, indicating the interaction term is valuable.
- All  $\beta$  terms have t—statistic significance of approximately 0.001 which is extremely significant.
- $\beta_0 = 6.75$ ,  $\beta_{TV} = 0.019$ ,  $\beta_{Radio} = 0.029$  and  $\beta_{TV:Radio} = 0.001$ , indicating that there is a favourable relationship between TV and Radio advertising ( $\beta_{TV:Radio} > 0$ ), and that additional spending on Radio results in more Sales than the same spending on TV ( $\beta_{Radio} > \beta_{TV}$ ).

- Trying powers of the Radio and TV greater than 1 did not offer much more.
- However, by adding the TV,Radio interaction so that the model became "Sales ~ TV + Radio + TV:Radio" or equivalently "Sales ~ TV \* Radio", the loss decreased significantly, indicating the interaction term is valuable.
- All  $\beta$  terms have t-statistic significance of approximately 0.001 which is extremely significant.
- $\beta_0 = 6.75$ ,  $\beta_{TV} = 0.019$ ,  $\beta_{Radio} = 0.029$  and  $\beta_{TV:Radio} = 0.001$ , indicating that there is a favourable relationship between TV and Radio advertising ( $\beta_{TV:Radio} > 0$ ), and that additional spending on Radio results in more Sales than the same spending on TV ( $\beta_{Radio} > \beta_{TV}$ ).
- Spending on Newspaper advertising should be discontinued as its contribution to Sales is insignificant (indistinguishable from random noise).

### Case Study 4: Credit balances - overview

#### Introducing

- the sklearn approach to regression (we used statsmodels with the Diamonds and Advertising data)
- non-numeric explanatory variables like gender and ethnicity
- more advanced regression modelling, e.g., handling correlated variables

Income Limit Rating Cards Age Education Gender Student Married Ethnicity Ralance

Note the presence of some categorical attributes (Gender, Student, Married, Ethnicity). These can participate in linear regression models to predict a numeric response, but must be coded first. For example, Gender can become an indicator (0,1)-valued variable of the form IsFemale. Ethnicity has 3 levels and is replaced by 3-1=2 indicator variables.

• the purpose of the analysis is to predict credit balances.

- the purpose of the analysis is to predict credit balances.
- Basic exploratory data techniques (histograms) soon indicated that there were 2 cohorts

- the purpose of the analysis is to predict credit balances.
- Basic exploratory data techniques (histograms) soon indicated that there were 2 cohorts
  - 1 those who do not use their cards and/or clear their balance each month

  - 1 those who do not use their cards and/or clear their balance each month
  - those who use their cards and have nonzero balances
- Removing data relating to the first cohort meant that the remaining data looked more cohesive and also made linear regression easier
- Take-away: look for inconsistent subsets in the data, remove them if possible

• Correlations between predictors are relatively high, but that between "Limit" and "Rating" is 1

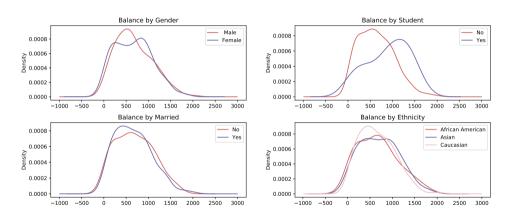

- Correlations between predictors are relatively high, but that between "Limit" and "Rating" is 1
- Generally, customers with a high rating are allowed to have high credit limits

- Correlations between predictors are relatively high, but that between "Limit" and "Rating" is 1
- Generally, customers with a high rating are allowed to have high credit limits
- Conversely, customers will not be allowed high credit limits unless they have a high credit rating

- Correlations between predictors are relatively high, but that between "Limit" and "Rating" is 1
- Generally, customers with a high rating are allowed to have high credit limits
- Conversely, customers will not be allowed high credit limits unless they have a high credit rating
- "Limit" was removed from the data used for analysis

- Correlations between predictors are relatively high, but that between "Limit" and "Rating" is 1
- Generally, customers with a high rating are allowed to have high credit limits
- Conversely, customers will not be allowed high credit limits unless they have a high credit rating
- "Limit" was removed from the data used for analysis
- Take-away: remove correlated attributes, because they increase the standard error (hence variance) and make the solver's job much more difficult

### Case Study 4: Credit balances - Contribution of Categorical Variables

Which of these categorical attributes has a significant effect on Balance?

# Case Study 4: Credit balances - Model building

- Using forward selection as before, the best model was found to be "Balance  $\sim$  poly(Income,2) + Rating + Age + Student + Income:Rating"
- Could also use Backward Elimination to prune from a complex model
- For this data, high correlations between features can cause difficulties we need techniques to handle this

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

How it shows up: The condition score is large and several model coefficients take large values with opposite signs. Sometimes the solver gives up.

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

How it shows up: The condition score is large and several model coefficients take large values with opposite signs. Sometimes the solver gives up.

Solution options:

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

How it shows up: The condition score is large and several model coefficients take large values with opposite signs. Sometimes the solver gives up.

#### Solution options:

 Remove selected features from the model (simple, does not always work and requires care)

## Difficulties caused by correlated features

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

How it shows up: The condition score is large and several model coefficients take large values with opposite signs. Sometimes the solver gives up.

#### Solution options:

- Remove selected features from the model (simple, does not always work and requires care)
- Use dimensionality reduction (linear PCA) to derive an uncorrelated subset of the features with least loss in explanatory power (principal components can be opaque)

## Difficulties caused by correlated features

The Problem: Several features are highly correlated, so the solver has difficulty assigning an importance independently to each.

How it shows up: The condition score is large and several model coefficients take large values with opposite signs. Sometimes the solver gives up.

#### Solution options:

- Remove selected features from the model (simple, does not always work and requires care)
- Use dimensionality reduction (linear PCA) to derive an uncorrelated subset of the features with least loss in explanatory power (principal components can be opaque)
- Use *regularisation*, to "penalise" large model coefficients (solve a related problem with a different loss function)

Add regularisation constraints to make the model work:  $\min_{\beta} \|\epsilon\|_2^2 + \lambda p(\beta)$ 

Options are

Add *regularisation* constraints to make the model work:  $\min_{\beta} \|\epsilon\|_{2}^{2} + \lambda p(\beta)$ 

- Options are
  - **①** Ridge Regression where the penalty term takes the form  $p(\beta) = \|\beta\|_2$

Add *regularisation* constraints to make the model work:  $\min_{\beta} \|\epsilon\|_{2}^{2} + \lambda p(\beta)$ 

- Options are
  - **1** Ridge Regression where the penalty term takes the form  $p(\beta) = \|\beta\|_2$
  - **②** Lasso where the penalty term takes the form  $p(\beta) = \|\beta\|_1$

Add regularisation constraints to make the model work:  $\min_{\beta} \|\epsilon\|_2^2 + \lambda p(\beta)$ 

- Options are
  - **1** Ridge Regression where the penalty term takes the form  $p(\beta) = \|\beta\|_2$
  - ② Lasso where the penalty term takes the form  $p(\beta) = \|\beta\|_1$
- Regularisation has a metaparameter  $\lambda$  the challenge is to choose a suitable value

Add regularisation constraints to make the model work:  $\min_{\beta} \|\epsilon\|_2^2 + \lambda p(\beta)$ 

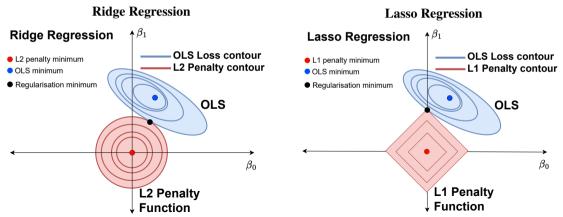

- Options are
  - **1** Ridge Regression where the penalty term takes the form  $p(\beta) = ||\beta||_2$
  - ② Lasso where the penalty term takes the form  $p(\beta) = \|\beta\|_1$
- Regularisation has a metaparameter  $\lambda$  the challenge is to choose a suitable value
  - if too large: tries less to match the data, increases the bias

Add regularisation constraints to make the model work:  $\min_{\beta} \|\epsilon\|_2^2 + \lambda p(\beta)$ 

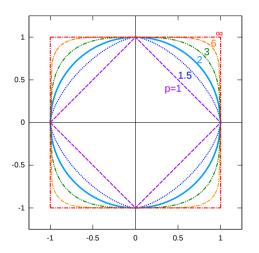

- Options are
  - **1** Ridge Regression where the penalty term takes the form  $p(\beta) = ||\beta||_2$
  - ② Lasso where the penalty term takes the form  $p(\beta) = \|\beta\|_1$
- Regularisation has a metaparameter  $\lambda$  the challenge is to choose a suitable value
  - if too large: tries less to match the data, increases the bias
  - if too small: tries too hard to match the data so  $\beta \to \infty$  and increases the variance

## Ridge vs Lasso Regression

Because lasso regression favours the "corners" in parameter space, it tends to set some parameter values to 0 (essentially dropping the associated features). This has the added benefit of making the model smaller and easier to interpret.

• Choose a set of candidate  $\lambda$  values

- Choose a set of candidate  $\lambda$  values
- ullet For each candidate  $\lambda$ , use K-fold cross-validation on data subsets to estimate the prediction error for the regularised fit with that  $\lambda$

- Choose a set of candidate  $\lambda$  values
- ullet For each candidate  $\lambda$ , use K-fold cross-validation on data subsets to estimate the prediction error for the regularised fit with that  $\lambda$
- **3** Choose the  $\lambda$  for which the expected error is least

- Choose a set of candidate  $\lambda$  values
- ullet For each candidate  $\lambda$ , use K-fold cross-validation on data subsets to estimate the prediction error for the regularised fit with that  $\lambda$
- **Output** Choose the  $\lambda$  for which the expected error is least
- Now fit all the training data again with this choice of  $\lambda$

- Choose a set of candidate  $\lambda$  values
- ullet For each candidate  $\lambda$ , use K-fold cross-validation on data subsets to estimate the prediction error for the regularised fit with that  $\lambda$
- **Olympia** Choose the  $\lambda$  for which the expected error is least
- Now fit all the training data again with this choice of  $\lambda$

Note that lasso (but not ridge regression) can set particular  $\beta_j$  to 0 (effectively removing them from the model), so it operates more like the *backwards elimination* model building procedure in terms of creating a more frugal model having fewer terms.

- Choose a set of candidate  $\lambda$  values
- ullet For each candidate  $\lambda$ , use K-fold cross-validation on data subsets to estimate the prediction error for the regularised fit with that  $\lambda$
- **3** Choose the  $\lambda$  for which the expected error is least
- **1** Now fit all the training data again with this choice of  $\lambda$

Note that lasso (but not ridge regression) can set particular  $\beta_j$  to 0 (effectively removing them from the model), so it operates more like the *backwards elimination* model building procedure in terms of creating a more frugal model having fewer terms.

Ridge regression downweights certain terms but does not set them to zero. However, it can be more performant, because it keeps some contribution from each feature.

## Recall: Attribute independence in Multivariate Data

#### Definition 3 (Covariance)

 $\sigma_{12} = E[(X_1 - \mu_1)(X_2 - \mu_2)]$ . In words, for two attributes  $X_1$  and  $X_2$ , with means  $\mu_1$  and  $\mu_2$ , respectively,  $\sigma_{12}$  is a measure of the linear dependence between them. If they are independent, we can show that  $\sigma_{12} = 0$ .

#### Definition 4 ((Variance-)Covariance Matrix)

When there are n numeric attributes, there are  $n \times n$  pairs of covariances  $\sigma_{ij}$ ,  $i = 1, \ldots, n$ ;  $j = 1, \ldots, n$ . The resulting covariance matrix is symmetric and diagonally dominant. This matrix captures the covariance structure of the set of n attributes  $\{X_i\}$ .

Sometimes it is convenient to work with the correlation matrix, which is a scaled version pf the covariance matrix, with elements  $\rho_{ij} = \frac{\sigma_{ij}}{\sigma_i \sigma_j}$ , which is scaled so that all the diagonal elements are 1 and the off diagonal elements satisfy  $-1 < \rho_{ij} < 1$ . If two attributes are highly correlated, adding the second into the model does not increase the explanatory power of the model. Therefore, it pays to determine the covariance matrix from the data before building any models.

• Sometimes it is possible to use intuition to reduce the dimension, by omitting selected attributes.

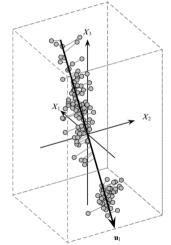

- Sometimes it is possible to use intuition to reduce the dimension, by omitting selected attributes.
- Another possibility is to look for groups of correlated attributes (c.f., *mediation*), such as the London and Birmingham measles cases above, and just choose 1 of these.

- Sometimes it is possible to use intuition to reduce the dimension, by omitting selected attributes.
- Another possibility is to look for groups of correlated attributes (c.f., *mediation*), such as the London and Birmingham measles cases above, and just choose 1 of these.
- More generally, there are techniques that search for a subspace with specified dimension d' of the attributes that captures most of the variance of the full set of attributes having dimension d, where d' < d (often  $d' \ll d$ ).

 $u_1, u_2$ 

• Although the data has dimension d = 3, it is possible to find the line (on the left; d = 1) and plane (on the right, d = 2) which retain most of the variance of the data after it has been projected onto this lower dimensional subspace.

- Although the data has dimension d = 3, it is possible to find the line (on the left; d = 1) and plane (on the right, d = 2) which retain most of the variance of the data after it has been projected onto this lower dimensional subspace.
- First compute the transformations needed to align the training data with the selected subspace.

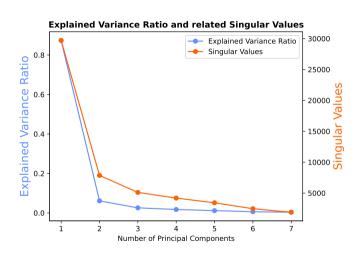

- Although the data has dimension d = 3, it is possible to find the line (on the left; d = 1) and plane (on the right, d = 2) which retain most of the variance of the data after it has been projected onto this lower dimensional subspace.
- First compute the transformations needed to align the training data with the selected subspace.
- Train the model using the transformed training data and the transformed features (principal components of the original features)

- Apply the inverse projection to the data, restoring it to its original orientation. However, because of the use of projections, it is not the same as the original data the round-trip is "lossy".
- However, it is helpful to interpret the results in terms of the original attributes.

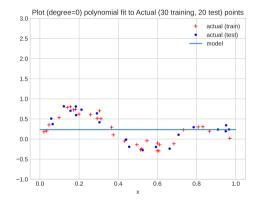

### PCA example

The plot shows that the first 3 singular values (associated with principal components  $u_1, u_2, u_3$ ) capture the bulk of the variance in the training set. Therefore, three attributes, which are transformations of the other 7, are sufficient. You could interpret those attributes as representing the measles outbreaks in three archetypal English cities...

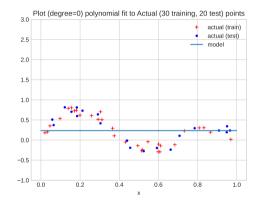

This youtube video describes PCA concepts well.

# Returning to the problematic example

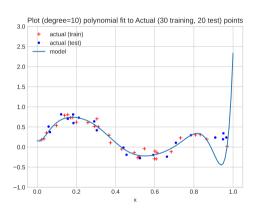

Degree 0 (constant) fit: high bias, low variance

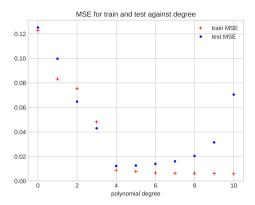

# Returning to the problematic example

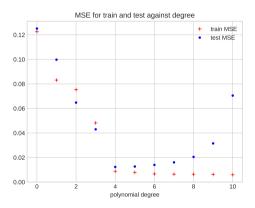

Degree 0 (constant) fit: high bias, low variance

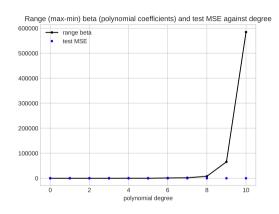

Degree 10 (up to  $x^{10}$ ) fit: low bias, high variance

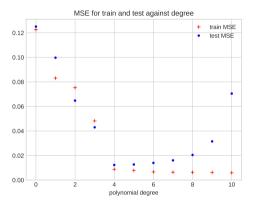

Train MSE decreases with degree, Test MSE decreases, then increases

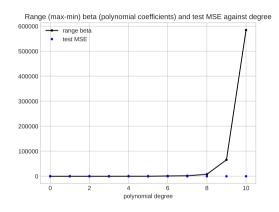

Train MSE decreases with degree, Test MSE decreases, then increases

Polynomial coefficient range (max-min) increases dramatically with degree due to overfitting.

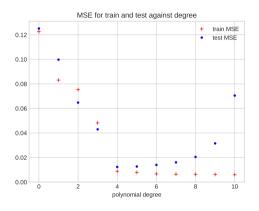

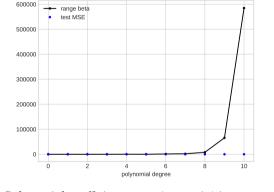

Train MSE decreases with degree, Test MSE decreases, then increases

Polynomial coefficient range (max-min) increases dramatically with degree due to overfitting.

Is there any way we can use high-degree polynomials?

Range (max-min) beta (polynomial coefficients) and test MSE against degree

Train MSE decreases with degree, Test MSE decreases, then increases

Polynomial coefficient range (max-min) increases dramatically with degree due to overfitting.

Is there any way we can use high-degree polynomials?

Yes, if we add regularisation...

# Review and summary

- Linear regression is one of the foundations of data mining
- It has two phases, of which the first (learning) is generally the most challenging
- It has many variants, so is quite flexible, but flexibility can be abused!
- Careful validation and model building is essential for success it is an extension of the exploratory work done earlier in the process
- In machine learning, prediction error is the main focus, but you need to be aware of other considerations such as
  - model parsimony (keep them as small as possible!): faster at both training and evaluation time
  - the bias-variance dilemma: avoid overfitting and underfitting remember, your model needs to generalise well from the training to the test set
  - omodel interpretability: some models are easier to understand because the terms in the model represent concepts from the domain the data is from

### Some Additional Resources

- Book: Introduction to Statistical Learning with R (2013) by James, Gareth and Witten, Daniela and Hastie, Trevor and Tibshirani, Robert.
  - I strongly recommend that you read Chapter 3 of the book, as it is very well written and available online for free.
- Kaggle notebooks relating to the datasets addressed this week. There are many, but searching Kaggle should provide nice examples of data mining in action.
- I wrote a report on linear regression that has been added to moodle.
